Assumptions Not Specifically Mentioned

1. Each group should have an equal chance of doing well, i.e. no supergroups

Factors of Success

Three factors to predict student group success are

1. Course grade - grade of student in the course
2. Experience - whether the student has done a similar project
3. Knowledge on Topic - how well the student knows the details of the task at hand

Collection of Data

The course administrator should have no problem collecting course grade for the students. The other factors can be collected by survey/questionnaire or simple show of hands during class.

```
# Generating random student data
set.seed(123456)
stu_data <- data.frame(grade = rnorm(12, mean=0.80, sd=0.1),
                        experience = sample(0:1, size=12, replace=TRUE),
                        knowledge = sample.int(5, size=12, replace=TRUE))

# Ensuring max grade of 1 and rounding to two places
library(dplyr)
```

```
##
## Attaching package: 'dplyr'

## The following objects are masked from 'package:stats':
##
##   filter, lag
```

```
## The following objects are masked from 'package:base':
##
## intersect, setdiff, setequal, union

stu_data <- stu_data %>% mutate(grade=if_else(grade>1, 1, round(grade, 2)))
head(stu_data)
```

```
##   grade experience knowledge
## 1  0.88          1          3
## 2  0.77          0          4
## 3  0.76          0          3
## 4  0.81          1          2
## 5  1.00          1          5
## 6  0.88          0          2
```

Decision Variables

The decision variables are the members of the groups. $g_{i,j}$ denotes whether the j th student is in the i th group

Objective Function

The objective of this project is to maximize individual group chance success. Since the groups will have equal chance of success we only need the success chance of one group in the objective function: **MAX** $Z = q_1$ letting q_i denote the i th group's chance of success. We can define chance of success based on the factors above. To keep things simple, let's define $q_i = \sum_j x_j + e_j + 0.2k_j$ where x_j is the j th student's grade, e_j is whether the j th student has similar prior experience, and k_j is the student's reported knowledge of the task at hand, for all j students in group i . The coefficients may be adjusted as necessary.

Constraints

The constraints of the model are the following

- * All groups should be about equally likely to succeed,
- * All groups have exactly 3 members * Members are to be in exactly one group

```
library(lpSolveAPI)

model <- read.lp("Student.lp")
solve(model)

## [1] 0

get.objective(model)

## [1] 5.84

get.variables(model)

## [1] 1 0 0 0 0 0 0 1 0 1 0 0 0 1 1 0 1 0 0 0 0 0 0 0 0 0 0 1 0 0 1 0 0 0 1 0 0 0
## [39] 0 0 0 1 0 0 1 0 0 1
```

Group decisions

Below are the decisions for where each student should end up:

Group 1: Students 1, 8, 10

Group 2: Students 2, 3, 5

Group 3: Students 4, 7, 11

Group 4: Students 6, 9, 12
